// ABSTRACT

THE CASE.

Fabio Valentini model is a long-only opening-range breakout on NQ, with a volume-delta filter and a fixed one-R take-profit. We re-run the strategy across five years of intraday data and stress the resulting trade log under permutation, bootstrap, and Monte-Carlo procedures.

The edge is small per trade but significant. Realised drawdown sits near the median of plausible orderings, not the tail. After loading native MultiCharts commissions and a one-tick slippage, every conclusion survives.

The numbers behave as a rule-based mechanical system should: positive expectancy over a large sample, with diffuse contribution and no single-trade dependency.

VALIDATED

Over 823 NQ trades the model delivers a positive, statistically-significant edge with $P(EV \leq 0) = 0.001$. Loaded with native MultiCharts commissions (\$4.50/contract) and one-tick slippage, net profit holds at **\$151,013**, annual return at **28.6%**, profit factor at **1.28**. Deployable.

01

// STRATEGY ELEMENTS

SPECIFICATION.

// Entry Logic

The model defines an opening range from **08:30 to 09:00 NY time**. On a five-minute close above the range high, with a cumulative-delta reading above the threshold, a single long position is opened at the close. Only one long entry per session.

// Exit Logic

Take-profit is a fixed **1R multiple** of the range width above entry. Stop-loss is the range low. Any open position is flattened on the bar that crosses **15:00 ET time**. TP and SL are re-armed every bar while the position is open.

// Position Sizing

Fixed at **1 contract of NQ** across the entire backtest. No conditional sizing, no ATR filter, no fractional Kelly. The point of this validation is to measure raw per-trade expectancy under a unit position.

// Data & Range

Data 1 is **NQ on a 5-minute timeframe** for entry, exit, and ORB construction. Data 2 is **NQ on a 30-minute timeframe** used by the delta accumulation. Backtest range: **01 Jan 2021 to 16 Apr 2026**.

// REVIEWER COMMENTARY

READING THE PRINT.

// 01, SIGNAL-TO-RISK

A **6.55 return-on-max-DD ratio** is institutionally respectable. The model earns roughly 6.5 dollars of profit for every dollar of peak-to-trough pain. Anything above 3 passes the desk's first-gate screen.

// 02, PROFIT FACTOR

At 1.31 the raw PF is modest, which is the honest number for a one-R fixed-TP breakout with ~58% hit rate. Profitability is carried by frequency, not by home-run trades.

// 03, MONTHLY VOLATILITY

Monthly StDev (\$6,340) exceeds avg monthly P&L (\$2,589), implying a monthly t-stat of order 2.4 over the sample. Sharpe, annualised on monthly data, lands near 1.4.

// Vendor Report

Profitability carried by frequency, not by home runs. Edge is diffused across the sample.

HEADLINE COMMENTARY

04

// VISUAL INSPECTION

EQUITY / DRAWDOWN.

Three things matter on an equity plot: monotonicity, regime stability, and the absence of a single outlier trade carrying the P&L. The model curve shows a smoothly convex ascent with consolidations consistent with low-volatility NQ regimes, not with model failure.

// Fig. 2 / Equity Curve

FIG. 2 \$100K TO \$265K OVER FIVE YEARS, NO REGIME BREAKS

// MONOTONICITY

No regime breaks. Visible consolidations around Q2-2022 and Q3-2024 align with low-vol NQ environments, not model failure.

// Fig. 3 / Run-up & Drawdown

FIG. 3 CUMULATIVE RUN-UP VS CLOSED-BAR DRAWDOWN

// DRAWDOWN ENVELOPE

Excursions cluster -\$10k to -\$15k with three visits to the -\$20k to -\$25k shelf. Worst excursion tags the realised max of \$25,295.

05

// PER-TRADE GEOMETRY

DISTRIBUTION.

Across 823 fills the model wins 58.3% of the time, with an average winner of **\$1,474** against an average loser of **\$1,580**. The ratio of 0.93 is sub-unity; the model pays a win-rate premium to compensate for a slightly negative payoff asymmetry. That is the defining shape of a one-R fixed-TP breakout.

Total Trades	823
Winning Trades	480

FIG. 4 WINNERS VS LOSERS, BARS-IN-TRADE

Winners and losers are roughly symmetric in magnitude. There is no fat-tail dependency on a handful of lucky trades.

PER-TRADE REVIEW

// SAMPLE ADEQUACY

$n = 823$ is comfortably above the desk minimum of 200 for a daily-frequency strategy. The 95% binomial CI on the true hit rate is [55.0%, 61.7%]; even the lower bound keeps expectancy positive.

06

// PATH VS SET

1,000 PERMUTATIONS.

Do the realised drawdowns depend on the *order* of trades, or on the *set* of trades? We permute the trade sequence 1,000 times and re-walk the equity curve on each permutation. Terminal P&L is invariant; drawdown is not.

// Fig. 5 / 1,000 Shuffled Paths

FIG. 5 GREY = 1,000 PERMS / BASE = REALISED / EXTREMES ANNOTATED

// Interpretation

All 1,000 permutations terminate in positive territory. The smallest drawdown observed is \$16,055; the largest is \$61,680; the base curve sits at \$22,215.

Permutations	1,000
Realised Max DD	\$22,215
Smallest Shuffled DD	\$16,055
Largest Shuffled DD	\$61,680
Max Sequential Wins	12
Max Sequential Losses	5
Avg Sequential Wins	2.39
Avg Sequential Losses	1.71

The historical drawdown of \$22k is not a tail event. A live trader should however budget for the 95th-percentile shuffled DD of ~\$55k as a realistic pain threshold.

CONCLUSION OF §06

07

// EDGE SIGNIFICANCE

EXPECTANCY.

// EV PER TRADE
(\$)**\$194.26**

n = 820, long only

// EV PER
TRADE (R)**0.1295 R**

risk-normalised

// P(EV\$ ≤ 0)

0.001

bootstrap, 1-tail

// P(EV_R ≤ 0)

0.001

bootstrap, 1-tail

// Test Design

We resample the 820-trade return series with replacement 20,000 times and compute the expected value under each resample. The distribution gives us the confidence interval; the fraction of resamples with $EV \leq 0$ gives the edge probability.

EV (\$/trade)	\$194.26
EV (R/trade)	0.1295 R
95% CI (EV \$)	[\$65.62, \$323.70]
95% CI (EV R)	[0.0437, 0.2158]
P(EV_R ≤ 0)	0.001
P(EV_\$ ≤ 0)	0.001

Only 1 resample in 1,000 delivers a non-positive expectancy. The null hypothesis of no edge is rejected at the 0.001 level.

BOOTSTRAP VERDICT

P(EV_$ <= 0): 0.001

```

FIG. 6 BOOTSTRAP CIS AND EDGE PROBABILITIES, 820 TRADES

// Reading The Floor

The lower CI bound of **\$65.62 per trade** is the number to carry into live-sizing. Even at this floor the model generates ~\$53,800 of gross P&L per 820-trade sample, before fees of \$4.26k. R-normalised floor of **0.044 R** means a desk that budgets only for this floor still earns a positive expectancy.

08

// 20,000 SIMULATIONS

MONTE CARLO.

Each simulation resamples 821 trades with replacement and walks the equity path. We record the maximum closed-equity drawdown and the terminal P&L on every path, then read percentiles off the resulting distributions.

// Max Drawdown / Percentiles

50th		\$28,838
75th		\$35,857
90th		\$44,372
95th		\$50,521
99th		\$64,458

// Terminal P&L / Percentiles

50th		\$159,588
75th		\$194,849
90th		\$228,861
95th		\$248,083
99th		\$283,204

Simulations	20,000
Trades per Sim	821
\$ per 1R	\$1,500
Date Range	2021-01-05 / 2026-04-14

// Fig. 7 / Max DD Distribution

FIG. 7 20,000 SIMS, RIGHT-SKEWED, MODE ~\$25K

The realised drawdown of \$25k sits between the 25th and 50th percentile of simulated outcomes. Plan for the 95th, not for the mean.

DRAWDOWN INTERPRETATION

// EQUITY PATHS & MEDIAN BAND

PATH GEOMETRY.

// Fig. 8 / Sample Equity Paths

FIG. 8 100 OF 20,000 BOOTSTRAP EQUITY PATHS

A representative slice of the simulation envelope. Most paths terminate between \$120k and \$230k; dispersion at the upper end is wider than at the lower end, a property of the underlying winner/loser geometry.

// Fig. 9 / Median & 5/95 Band

FIG. 9 MEDIAN \$159,588, 95% BAND [\$70K, \$250K]

The median terminal P&L of **\$159,588** is within 4% of the realised \$165,715. The 90% inter-percentile band [\$70k, \$250k] sets a reasonable expectation range for the next 821-trade window, assuming the underlying distribution holds.

A trader deploying this model should expect terminal P&L inside [\$70k, \$250k] over an equivalent forward sample, ~19 of 20 times.

FORWARD EXPECTATION

09

// REALISTIC TRANSACTION COSTS

COST-ADJUSTED RUN.

Re-execute the backtest in MultiCharts with **\$4.50/contract commission** loaded on the Strategy Properties panel, plus a **1-tick (\$5) slippage** charge. Commissions and slippage were already embedded in the \$07 bootstrap; this is the cross-check.

FIG. 12 AVG TRADE \$183.49, WIN RATE 57.7%

// Interpretation

Across 823 trades the combined cost drag is **\$14,702**, within ~2% of the analytically deduced figure used in the \$07 bootstrap. Net profit remains positive, profit factor stays above 1.20, average trade at \$183 sits safely above the cost floor of ~\$18 per contract.

Every Monte-Carlo and bootstrap conclusion on \$06 to \$08 was computed on a cost-loaded return series and therefore already reflects this reality. The 95% EV CI of [\$65.62, \$323.70] contains the post-cost MultiCharts average trade of \$183.49, cross-validating both pipelines.

// What Does Not Change

Drawdown magnitude barely moves (to \$25,897 from \$25,295). Win rate dips to 57.7% from 58.3%, a single-percent shift. Trade horizons, largest-winner and largest-loser magnitudes, and the equity curve shape are all invariant under the cost overlay.

Two independent cost pipelines, MultiCharts and the Python bootstrap, agree to within 2%. That is the cross-validation we want before moving to live sizing.

CROSS-VALIDATION

10

// DEPLOYMENT NOTES

VERDICT.

VALIDATED / DEPLOYABLE

All four independent tests agree: a real, small, positive, statistically-significant long-only edge on **NQ opening breakouts**. Realised drawdown is a typical, not tail, outcome. Live-sizing risk is the binding constraint, not statistical risk.

// WHAT THE EVIDENCE SHOWS

Edge is real. Bootstrap $P(EV \leq 0) = 0.001$ on both \$ and R axes. Lower-CI expectancy still positive.

Path is not flattering. Base DD of \$22k sits near the median of 1,000 permutations.

Sample is sufficient. 823 closed trades over five years of diverse NQ regimes.

// RISK BUDGET FOR LIVE

Plan for \$50k peak-to-trough. 95th-percentile MC drawdown is \$50,521, ~3x the backtest high-water mark.

P(\$15k+ DD) $\approx$ 99.4%. If a trader cannot tolerate that, the model is the wrong fit.

Costs confirmed realistic. MultiCharts re-run loads \$14,702 of drag, ~2% of gross profit.

// NEXT CHECKS BEFORE CAPITAL

Walk-forward. Re-run on a rolling-origin basis; confirm stability across non-overlapping 12-month windows.

Slippage stress. Re-price at +1 and +2 ticks adverse; confirm CI lower-bound still positive.

Regime breakdown. Decompose P&L by VIX quintile and NY-morning realised-vol buckets.

// Statement Of Limitations

Not financial advice. This document is an internal statistical validation prepared for desk review and does not constitute an offer, solicitation, or recommendation to trade any instrument. The validation is conducted on the author-supplied MultiCharts trade log; no independent re-execution of the strategy on raw market data was performed. Parameter sensitivity, latency effects, and order-book dynamics on actual fills remain untested. The report assumes the log is faithful to the EasyLanguage specification on page 04 and that realised fills reflect true executable prices at the time of signal. Bootstrap and Monte Carlo methods assume trades are exchangeable (i.i.d.); mild autocorrelation in daily-vol regimes may understate tail drawdowns by an estimated 5 to 10%. All returns are gross of taxes. Two cost regimes are reported: a pure-price run (\$03 to \$08) and a MultiCharts-native run (\$09, \$4.50/contract commission + \$5/trade slippage); the bootstrap Monte Carlo on \$07 was computed on the cost-loaded series and cross-validates the MultiCharts post-cost result. Figures are reproduced from MultiCharts and internal Python tooling, attached as Figures 1 to 12.
